# Background and Motivation

Many physical and economic systems should be and in fact have been successfully modeled by discontinuous Markov processes. Discontinuous Markov processes are also very important from a theoretical point of view, since they contain stable processes, relativistic stable processes and jump diffusions as special cases.

Due to their importance both in theory and in applications, discontinuous Markov processes have been receiving intensive study in recent years.

# Background and Motivation

Many physical and economic systems should be and in fact have been successfully modeled by discontinuous Markov processes. Discontinuous Markov processes are also very important from a theoretical point of view, since they contain stable processes, relativistic stable processes and jump diffusions as special cases.

Due to their importance both in theory and in applications, discontinuous Markov processes have been receiving intensive study in recent years.

General Markov processes have discontinuous sample paths. A Markov process having continuous sample paths is called a diffusion.

Diffusion processes in  $\mathbb{R}^d$  and second order elliptic differential operators on  $\mathbb{R}^d$  are closely related in the following sense. For a large class of second order elliptic differential operators  $\mathcal{L}$  on  $\mathbb{R}^d$ , there is a diffusion process  $X$  in  $\mathbb{R}^d$  associated with it so that  $\mathcal{L}$  is the infinitesimal generator of  $X$ , and vice versa.

The connection between  $\mathcal{L}$  and  $X$  can also be seen as follows. The fundamental solution  $p(t, x, y)$  of  $\partial_t u = \mathcal{L}u$  (also called the heat kernel of  $\mathcal{L}$ ) is the transition density of  $X$ .

Thus obtaining sharp two-sided estimates for  $p(t, x, y)$  is a fundamental problem in both analysis and probability theory.

Two-sided heat kernel estimates for diffusions in  $\mathbb{R}^d$  have a long history and many beautiful results have been established. Among the main contributors are: D. G. Aronson, J. Nash, E. B. Davies.

Due to the complication near the boundary, two-sided estimates on the transition density of killed diffusions in a domain  $D$  (equivalently, the Dirichlet heat kernel) have been established only recently. See Davies (87), Zhang (02) for the case of bounded  $C^{1,1}$  domains.

The infinitesimal generator of a discontinuous Markov process in  $\mathbb{R}^d$  is no longer a differential operator but rather a non-local (or integro-differential) operator  $\mathcal{L}$ . For instance, the infinitesimal generator of a rotationally symmetric  $\alpha$ -stable process in  $\mathbb{R}^d$  with  $\alpha \in (0, 2)$  is a fractional Laplacian operator  $\Delta^{\alpha/2} := -(-\Delta)^{\alpha/2}$ .

Recently in [CKS10, JEMS], we obtained sharp two-sided estimates for the heat kernel of the fractional Laplacian  $\Delta^{\alpha/2}$  in  $D$  with zero exterior condition (or equivalently, the transition density function of the symmetric  $\alpha$ -stable process killed upon exiting  $D$ ) for any  $C^{1,1}$  open set  $D \subset \mathbb{R}^d$  with  $d \geq 1$ . As far as we know, this was the first time sharp two-sided estimates were established for Dirichlet heat kernels of non-local operators.

For instance, the infinitesimal generator of a rotationally symmetric  $\alpha$ -stable process in  $\mathbb{R}^d$  with  $\alpha \in (0, 2)$  is a fractional Laplacian operator  $\Delta^{\alpha/2} := -(-\Delta)^{\alpha/2}$ .

Recently in [CKS10, JEMS], we obtained sharp two-sided estimates for the heat kernel of the fractional Laplacian  $\Delta^{\alpha/2}$  in  $D$  with zero exterior condition (or equivalently, the transition density function of the symmetric  $\alpha$ -stable process killed upon exiting  $D$ ) for any  $C^{1,1}$  open set  $D \subset \mathbb{R}^d$  with  $d \geq 1$ . As far as we know, this was the first time sharp two-sided estimates were established for Dirichlet heat kernels of non-local operators.

Since then, studies on this topic have been growing rapidly. The ideas of [CKS10, JEMS] have been adapted to establish two-sided heat kernel estimates of other discontinuous Markov processes, like censored stable processes [CKS10, PTRF] in open subsets of  $\mathbb{R}^d$ .

In this talk, I will present sharp two-sided estimates on the Dirichlet heat kernels of relativistic stable processes in  $C^{1,1}$  domains of  $\mathbb{R}^d$ .

- 5 Dirichlet Heat kernel estimates in exterior open set

For  $\alpha \in (0, 2]$ , a symmetric  $\alpha$ -stable process  $X$  on  $\mathbb{R}^d$  is a Lévy process such that for any  $t \geq 0$  and  $\xi \in \mathbb{R}^d$

$$\mathbb{E}[\exp(i\xi \cdot (X_t - X_0))] = \exp(-t|\xi|^\alpha).$$

When  $\alpha = 2$ , it reduces to a Brownian motion.

The infinitesimal generator of a symmetric  $\alpha$ -stable process  $Y$  in  $\mathbb{R}^d$  is the fractional Laplacian  $\Delta^{\alpha/2}$ , which can be written as

$$\Delta^{\alpha/2}u(x) = \lim_{\varepsilon \downarrow 0} \int_{\{y \in \mathbb{R}^d: |y-x| > \varepsilon\}} (u(y) - u(x)) \frac{\mathcal{A}(d, \alpha)}{|x-y|^{d+\alpha}} dy,$$

where  $\mathcal{A}(d, \alpha) := \alpha 2^{\alpha-1} \pi^{-d/2} \Gamma(\frac{d+\alpha}{2}) \Gamma(1 - \frac{\alpha}{2})^{-1}$ .

For  $\alpha \in (0, 2]$ , a symmetric  $\alpha$ -stable process  $X$  on  $\mathbb{R}^d$  is a Lévy process such that for any  $t \geq 0$  and  $\xi \in \mathbb{R}^d$

$$\mathbb{E}[\exp(i\xi \cdot (X_t - X_0))] = \exp(-t|\xi|^\alpha).$$

When  $\alpha = 2$ , it reduces to a Brownian motion.

The infinitesimal generator of a symmetric  $\alpha$ -stable process  $Y$  in  $\mathbb{R}^d$  is the fractional Laplacian  $\Delta^{\alpha/2}$ , which can be written as

$$\Delta^{\alpha/2}u(x) = \lim_{\varepsilon \downarrow 0} \int_{\{y \in \mathbb{R}^d: |y-x| > \varepsilon\}} (u(y) - u(x)) \frac{\mathcal{A}(d, \alpha)}{|x-y|^{d+\alpha}} dy,$$

where  $\mathcal{A}(d, \alpha) := \alpha 2^{\alpha-1} \pi^{-d/2} \Gamma(\frac{d+\alpha}{2}) \Gamma(1 - \frac{\alpha}{2})^{-1}$ .

Let  $p(t, x, y)$  be the transition density of  $X$ . When  $d > \alpha$ , the potential density (also called the Green function) of  $X$

$$G(x, y) = \int_0^\infty p(t, x, y) dt = C(d, \alpha) \frac{1}{|x - y|^{d-\alpha}}$$

which is the Riesz kernel.

Symmetric stable processes have some nice properties. For example it satisfies the following scaling property: For any  $a > 0$ ,  $\{a^{-1/\alpha}(X_{at} - X_0) : t \geq 0\}$  has the same law as  $\{X_t - X_0 : t \geq 0\}$ . In terms of the transition density, this means

$$p(t, x, y) = a^d p(at, a^{1/\alpha}x, a^{1/\alpha}y).$$

However, a symmetric  $\alpha$ -stable process, for  $\alpha \in (0, 2)$ , always have infinite variance. When  $\alpha \in (0, 1]$ , it also have infinite mean.

Let  $p(t, x, y)$  be the transition density of  $X$ . When  $d > \alpha$ , the potential density (also called the Green function) of  $X$

$$G(x, y) = \int_0^\infty p(t, x, y) dt = C(d, \alpha) \frac{1}{|x - y|^{d-\alpha}}$$

which is the Riesz kernel.

Symmetric stable processes have some nice properties. For example it satisfies the following scaling property: For any  $a > 0$ ,  $\{a^{-1/\alpha}(X_{at} - X_0) : t \geq 0\}$  has the same law as  $\{X_t - X_0 : t \geq 0\}$ . In terms of the transition density, this means

$$p(t, x, y) = a^d p(at, a^{1/\alpha}x, a^{1/\alpha}y).$$

However, a symmetric  $\alpha$ -stable process, for  $\alpha \in (0, 2)$ , always have infinite variance. When  $\alpha \in (0, 1]$ , it also have infinite mean.

Let  $p(t, x, y)$  be the transition density of  $X$ . When  $d > \alpha$ , the potential density (also called the Green function) of  $X$

$$G(x, y) = \int_0^\infty p(t, x, y) dt = C(d, \alpha) \frac{1}{|x - y|^{d-\alpha}}$$

which is the Riesz kernel.

Symmetric stable processes have some nice properties. For example it satisfies the following scaling property: For any  $a > 0$ ,  $\{a^{-1/\alpha}(X_{at} - X_0) : t \geq 0\}$  has the same law as  $\{X_t - X_0 : t \geq 0\}$ . In terms of the transition density, this means

$$p(t, x, y) = a^d p(at, a^{1/\alpha}x, a^{1/\alpha}y).$$

However, a symmetric  $\alpha$ -stable process, for  $\alpha \in (0, 2)$ , always have infinite variance. When  $\alpha \in (0, 1]$ , it also have infinite mean.

For any  $m \geq 0$ , a relativistic  $\alpha$ -stable process  $X^m$  on  $\mathbb{R}^d$  with weight  $m$  is a Lévy process such that for any  $t \geq 0$  and  $\xi \in \mathbb{R}^d$

$$\mathbb{E}[\exp(i\xi \cdot (X_t^m - X_0^m))] = \exp\left(-t\left(\left(|\xi|^2 + m^{2/\alpha}\right)^{\alpha/2} - m\right)\right).$$

When  $m = 0$ ,  $X^0$  is simply a (rotationally) symmetric  $\alpha$ -stable process on  $\mathbb{R}^d$ . The infinitesimal generator of  $X^m$  is

$$m - (-\Delta + m^{2/\alpha})^{\alpha/2}.$$

For any  $m \geq 0$ , a relativistic  $\alpha$ -stable process  $X^m$  on  $\mathbb{R}^d$  with weight  $m$  is a Lévy process such that for any  $t \geq 0$  and  $\xi \in \mathbb{R}^d$

$$\mathbb{E} [\exp (i \xi \cdot (X_t^m - X_0^m))] = \exp \left( -t \left( (|\xi|^2 + m^{2/\alpha})^{\alpha/2} - m \right) \right).$$

When  $m = 0$ ,  $X^0$  is simply a (rotationally) symmetric  $\alpha$ -stable process on  $\mathbb{R}^d$ . The infinitesimal generator of  $X^m$  is

$$m - (-\Delta + m^{2/\alpha})^{\alpha/2}.$$

When  $\alpha = 1$ , the infinitesimal generator reduces to

$$m - \sqrt{-\Delta + m^2}.$$

This operator was used by E. Lieb and his followers in studying the stability of matter.

Let  $p^m(t, x, y)$  be the transition density of  $X^m$ . The the function, called the 1-potential density of  $X^1$ :

$$\int_0^\infty e^{-t} p^1(t, x, y) dt$$

is the Bessel kernel.

When  $\alpha = 1$ , the infinitesimal generator reduces to

$$m - \sqrt{-\Delta + m^2}.$$

This operator was used by E. Lieb and his followers in studying the stability of matter.

Let  $p^m(t, x, y)$  be the transition density of  $X^m$ . The the function, called the 1-potential density of  $X^1$ :

$$\int_0^\infty e^{-t} p^1(t, x, y) dt$$

is the Bessel kernel.

The Lévy measure of  $X^m$  has a density

$$J^m(x, y) = \mathcal{A}(d, \alpha) |x - y|^{-d-\alpha} \psi(m^{1/\alpha} |x - y|)$$

where

$$\psi(r) := \int_0^\infty s^{\frac{d+\alpha}{2}-1} e^{-\frac{s}{4} - \frac{r^2}{s}} ds,$$

which is decreasing and is a smooth function of  $r^2$  satisfying  $\psi(r) \leq 1$  and

$$\psi(r) \asymp \phi(r) := e^{-r} (1 + r^{(d+\alpha-1)/2}) \quad \text{on } [0, \infty).$$

For  $m > 0$ ,  $X^m$  has moments of all orders, and it even has some exponential moments. In a small scale,  $X^m$  behaves like  $X^0$ , while in a larger scale,  $X^m$  behaves like Brownian motion.

The Lévy measure of  $X^m$  has a density

$$J^m(x, y) = \mathcal{A}(d, \alpha) |x - y|^{-d-\alpha} \psi(m^{1/\alpha} |x - y|)$$

where

$$\psi(r) := \int_0^\infty s^{\frac{d+\alpha}{2}-1} e^{-\frac{s}{4} - \frac{r^2}{s}} ds,$$

which is decreasing and is a smooth function of  $r^2$  satisfying  $\psi(r) \leq 1$  and

$$\psi(r) \asymp \phi(r) := e^{-r}(1 + r^{(d+\alpha-1)/2}) \quad \text{on } [0, \infty).$$

For  $m > 0$ ,  $X^m$  has moments of all orders, and it even has some exponential moments. In a small scale,  $X^m$  behaves like  $X^0$ , while in a larger scale,  $X^m$  behaves like Brownian motion.

For  $m > 0$ ,  $X^m$  does not satisfy any scaling invariance property. However, it does satisfy some sort of approximate scaling property: For any  $a > 0$ ,  $\{a^{-1/\alpha}(X_{at}^{m/a} - X_0^{m/a}), t \geq 0\}$  has the same law as  $\{X_t^m - X_0^m, t \geq 0\}$ .

In terms of transition densities, this means that for all  $t, a > 0$  and  $x, y \in D$ ,

$$p^m(t, x, y) = a^{d/\alpha} p^{m/a}(at, a^{1/\alpha}x, a^{1/\alpha}y).$$

For  $m > 0$ ,  $X^m$  does not satisfy any scaling invariance property. However, it does satisfy some sort of approximate scaling property: For any  $a > 0$ ,  $\{a^{-1/\alpha}(X_{at}^{m/a} - X_0^{m/a}), t \geq 0\}$  has the same law as  $\{X_t^m - X_0^m, t \geq 0\}$ .

In terms of transition densities, this means that for all  $t, a > 0$  and  $x, y \in D$ ,

$$p^m(t, x, y) = a^{d/\alpha} p^{m/a}(at, a^{1/\alpha}x, a^{1/\alpha}y).$$

Two-sided estimates on  $p(t, x, y)$  is classical. But two-sided estimates on  $p^m(t, x, y)$  is more recent.

For any  $m, c > 0$ , we define a function  $\tilde{\Psi}_{d,\alpha,m,c}(t, x, y)$  on  $(0, \infty) \times \mathbb{R}^d \times \mathbb{R}^d$  by

$$\begin{aligned} & \tilde{\Psi}_{d,\alpha,m,c}(t, x, y) \\ := & \begin{cases} t^{-d/\alpha} \wedge tJ^m(x, y), & \forall t \in (0, 1/m]; \\ m^{d/\alpha-d/2} t^{-d/2} \exp\left(-c^{-1}(m^{1/\alpha}|x-y| \wedge m^{2/\alpha-1} \frac{|x-y|^2}{t})\right), & \forall t \in (1/m, \infty). \end{cases} \end{aligned}$$

**Theorem [Chen-Kim-Kumagai], [CKS1]**

$$c_1^{-1} \tilde{\Psi}_{d,\alpha,m,1/c_1}(t, x, y) \leq p^m(t, x, y) \leq c_1 \tilde{\Psi}_{d,\alpha,m,c_1}(t, x, y).$$

Two-sided estimates on  $p(t, x, y)$  is classical. But two-sided estimates on  $p^m(t, x, y)$  is more recent.

For any  $m, c > 0$ , we define a function  $\tilde{\Psi}_{d,\alpha,m,c}(t, x, y)$  on  $(0, \infty) \times \mathbb{R}^d \times \mathbb{R}^d$  by

$$\tilde{\Psi}_{d,\alpha,m,c}(t, x, y) := \begin{cases} t^{-d/\alpha} \wedge tJ^m(x, y), & \forall t \in (0, 1/m]; \\ m^{d/\alpha-d/2} t^{-d/2} \exp\left(-c^{-1}(m^{1/\alpha}|x-y| \wedge m^{2/\alpha-1} \frac{|x-y|^2}{t})\right), & \forall t \in (1/m, \infty). \end{cases}$$

Theorem [Chen-Kim-Kumagai], [CKS1]

$$c_1^{-1} \tilde{\Psi}_{d,\alpha,m,1/c_1}(t, x, y) \leq p^m(t, x, y) \leq c_1 \tilde{\Psi}_{d,\alpha,m,c_1}(t, x, y).$$

Two-sided estimates on  $p(t, x, y)$  is classical. But two-sided estimates on  $p^m(t, x, y)$  is more recent.

For any  $m, c > 0$ , we define a function  $\tilde{\Psi}_{d,\alpha,m,c}(t, x, y)$  on  $(0, \infty) \times \mathbb{R}^d \times \mathbb{R}^d$  by

$$\tilde{\Psi}_{d,\alpha,m,c}(t, x, y) := \begin{cases} t^{-d/\alpha} \wedge tJ^m(x, y), & \forall t \in (0, 1/m]; \\ m^{d/\alpha-d/2} t^{-d/2} \exp\left(-c^{-1}(m^{1/\alpha}|x-y| \wedge m^{2/\alpha-1} \frac{|x-y|^2}{t})\right), & \forall t \in (1/m, \infty). \end{cases}$$

### Theorem [Chen-Kim-Kumagai], [CKS1]

$$c_1^{-1} \tilde{\Psi}_{d,\alpha,m,1/C_1}(t, x, y) \leq p^m(t, x, y) \leq c_1 \tilde{\Psi}_{d,\alpha,m,C_1}(t, x, y).$$

# Relativistic stable process in $D$

For any open set  $D$ , we use  $\tau_D^m := \inf\{t > 0 : X_t^m \notin D\}$  to denote the first exit time from  $D$  by  $X^m$ , and  $X^{m,D}$  to denote the subprocess of  $X^m$  killed upon exiting  $D$  (or, the killed relativistic stable process in  $D$  with mass  $m$ ). We will use  $p_D^m(t, x, y)$  to denote the transition density of  $X^{m,D}$ .

$p_D^m(t, x, y)$  has the following scaling property:

$$p_D^m(t, x, y) = b^{d/\alpha} p_{b^{1/\alpha}D}^{m/b}(bt, b^{1/\alpha}x, b^{1/\alpha}y) \quad \text{for every } t, b > 0, x, y \in D.$$

# Relativistic stable process in $D$

For any open set  $D$ , we use  $\tau_D^m := \inf\{t > 0 : X_t^m \notin D\}$  to denote the first exit time from  $D$  by  $X^m$ , and  $X^{m,D}$  to denote the subprocess of  $X^m$  killed upon exiting  $D$  (or, the killed relativistic stable process in  $D$  with mass  $m$ ). We will use  $p_D^m(t, x, y)$  to denote the transition density of  $X^{m,D}$ .

$p_D^m(t, x, y)$  has the following scaling property:

$$p_D^m(t, x, y) = b^{d/\alpha} p_{b^{1/\alpha}D}^{m/b}(bt, b^{1/\alpha}x, b^{1/\alpha}y) \quad \text{for every } t, b > 0, x, y \in D.$$

- 4 Dirichlet Heat kernel estimates in half-space-like open set
- 5 Dirichlet Heat kernel estimates in exterior open set

## Theorem [CKS1]

Suppose that  $D$  is a  $C^{1,1}$  open set. (i) For any  $m \in (0, M]$  and  $(t, x, y) \in (0, T] \times D \times D$ ,

$$\begin{aligned} & \frac{1}{C_1} \left( 1 \wedge \frac{\delta_D(x)^{\alpha/2}}{\sqrt{t}} \right) \left( 1 \wedge \frac{\delta_D(y)^{\alpha/2}}{\sqrt{t}} \right) \left( t^{-d/\alpha} \wedge \frac{t\phi(m^{1/\alpha}|x-y|)}{|x-y|^{d+\alpha}} \right) \\ & \leq p_D^m(t, x, y) \leq \\ & C_1 \left( 1 \wedge \frac{\delta_D(x)^{\alpha/2}}{\sqrt{t}} \right) \left( 1 \wedge \frac{\delta_D(y)^{\alpha/2}}{\sqrt{t}} \right) \left( t^{-d/\alpha} \wedge \frac{t\phi(m^{1/\alpha}|x-y|/(16))}{|x-y|^{d+\alpha}} \right), \end{aligned}$$

where  $\phi(r) = e^{-r}(1+r^{(d+\alpha-1)/2})$ .

(ii) Suppose in addition that  $D$  is bounded. for any  $m \in (0, M]$  and  $(t, x, y) \in [T, \infty) \times D \times D$ ,

$$p_D^m(t, x, y) \asymp e^{-t\lambda_1^{\alpha, m, D}} \delta_D(x)^{\alpha/2} \delta_D(y)^{\alpha/2},$$

where  $\lambda_1^{\alpha, m, D} > 0$  is the smallest eigenvalue of the restriction of  $(m^{2/\alpha} - \Delta)^{\alpha/2} - m$  in  $D$  with zero exterior condition.

Our estimates are uniform in  $m$  in the sense that the constants are independent of  $m \in (0, M]$ . Letting  $m \downarrow 0$  recovers the below sharp heat kernel estimates for symmetric  $\alpha$ -stable processes

### Theorem [CKS, JEMS10]

Suppose that  $D$  is a  $C^{1,1}$  open set. (i) For every  $T > 0$ , on  $(0, T] \times D \times D$

$$p_D^0(t, x, y) \asymp \left(1 \wedge \frac{\delta_D(x)^{\alpha/2}}{\sqrt{t}}\right) \left(1 \wedge \frac{\delta_D(y)^{\alpha/2}}{\sqrt{t}}\right) \left(t^{-d/\alpha} \wedge \frac{t}{|x-y|^{d+\alpha}}\right).$$

(ii) Suppose in addition that  $D$  is bounded. For every  $T > 0$ , on  $[T, \infty) \times D \times D$ ,

$$p_D^0(t, x, y) \asymp e^{-\lambda_1^{\alpha,0,D} t} \delta_D(x)^{\alpha/2} \delta_D(y)^{\alpha/2},$$

where  $\lambda_1^{\alpha,0,D} > 0$  is the smallest eigenvalue  $(-\Delta)^{\alpha/2}|_D$ .

Our estimates are uniform in  $m$  in the sense that the constants are independent of  $m \in (0, M]$ . Letting  $m \downarrow 0$  recovers the below sharp heat kernel estimates for symmetric  $\alpha$ -stable processes

### Theorem [CKS, JEMS10]

$$p_D^0(t, x, y) \asymp \left(1 \wedge \frac{\delta_D(x)^{\alpha/2}}{\sqrt{t}}\right) \left(1 \wedge \frac{\delta_D(y)^{\alpha/2}}{\sqrt{t}}\right) \left(t^{-d/\alpha} \wedge \frac{t}{|x-y|^{d+\alpha}}\right).$$

(ii) Suppose in addition that  $D$  is bounded. For every  $T > 0$ , on  $[T, \infty) \times D \times D$ ,

$$p_D^0(t, x, y) \asymp e^{-\lambda_1^{\alpha,0,D} t} \delta_D(x)^{\alpha/2} \delta_D(y)^{\alpha/2},$$

where  $\lambda_1^{\alpha,0,D} > 0$  is the smallest eigenvalue  $(-\Delta)^{\alpha/2}|_D$ .

# Difficulties and Ingredients

- two-sided estimates on  $p^m$ .
- the approximate scaling property
- the Lévy density of  $X^m$  does not have a simple form and has exponential decay rate as oppose to the polynomial decay rate of the Lévy density of symmetric stable process
- uniform Boundary Harnack principle and parabolic Harnack principle
- There exist positive constants  $R_0$  and  $C > 1$  depending only on  $d$  and  $\alpha$  such that for any  $m \in (0, \infty)$ , any ball  $B$  of radius  $r \leq R_0 m^{-1/\alpha}$ ,

$$C^{-1}G_B(x, y) \leq G_B^m(x, y) \leq CG_B(x, y), \quad x, y \in B.$$

$$V_D^\alpha(x, y) := \begin{cases} \left(1 \wedge \frac{\delta_D(x)^{\alpha/2} \delta_D(y)^{\alpha/2}}{|x-y|^\alpha}\right) |x-y|^{\alpha-d} & \text{when } d > \alpha, \\ \log \left(1 + \frac{\delta_D(x)^{1/2} \delta_D(y)^{1/2}}{|x-y|}\right) & \text{when } d = 1 = \alpha, \\ (\delta_D(x) \delta_D(y))^{(\alpha-1)/2} \wedge \frac{\delta_D(x)^{\alpha/2} \delta_D(y)^{\alpha/2}}{|x-y|} & \text{when } d = 1 < \alpha. \end{cases}$$

### Theorem [Ryznar], [CS]

Let  $D$  be a bounded  $C^{1,1}$ -open set in  $\mathbb{R}^d$  with  $d \geq 1$ . Then on  $D \times D$ , for every  $m \in (0, M]$  and  $(x, y) \in D \times D$ ,

$$G_D^m(x, y) \asymp V_D^\alpha(x, y).$$

$$V_D^\alpha(x, y) := \begin{cases} \left(1 \wedge \frac{\delta_D(x)^{\alpha/2} \delta_D(y)^{\alpha/2}}{|x-y|^\alpha}\right) |x-y|^{\alpha-d} & \text{when } d > \alpha, \\ \log \left(1 + \frac{\delta_D(x)^{1/2} \delta_D(y)^{1/2}}{|x-y|}\right) & \text{when } d = 1 = \alpha, \\ (\delta_D(x) \delta_D(y))^{(\alpha-1)/2} \wedge \frac{\delta_D(x)^{\alpha/2} \delta_D(y)^{\alpha/2}}{|x-y|} & \text{when } d = 1 < \alpha. \end{cases}$$

### Theorem [Ryznar], [CS]

where  $\phi(r) = e^{-r} (1 + r^{(d+\alpha-1)/2})$ .

## Theorem [CKS2]

Suppose  $D$  is a half-space-like  $C^{1,1}$  open set. For any  $M > 0$ , there exist  $C_i > 1 \geq 1$ ,  $i = 1, 2$ , such that for all  $m \in (0, M]$ ,

(i) if  $t \in (0, 1/m]$

$$\begin{aligned} C_1^{-1} \left( \frac{\delta_D(x)^{\alpha/2}}{\sqrt{t}} \wedge 1 \right) \left( \frac{\delta_D(y)^{\alpha/2}}{\sqrt{t}} \wedge 1 \right) \Psi_{d,\alpha,m,C_2}(t, x, y) &\leq p_D^m(t, x, y) \\ &\leq C_1 \left( \frac{\delta_D(x)^{\alpha/2}}{\sqrt{t}} \wedge 1 \right) \left( \frac{\delta_D(y)^{\alpha/2}}{\sqrt{t}} \wedge 1 \right) \Psi_{d,\alpha,m,1/C_2}(t, x, y) \end{aligned}$$

(ii) if  $t > 1/m$

$$\begin{aligned} C_1^{-1} \left( \frac{m^{(2-\alpha)/2\alpha} \delta_D(x) + \delta_D(x)^{\alpha/2}}{\sqrt{t}} \wedge 1 \right) \left( \frac{m^{(2-\alpha)/2\alpha} \delta_D(y) + \delta_D(y)^{\alpha/2}}{\sqrt{t}} \wedge 1 \right) \\ \times \Psi_{d,\alpha,m,C_2}(t, x, y) \\ \leq p_D^m(t, x, y) \leq \\ C_1 \left( \frac{m^{(2-\alpha)/2\alpha} \delta_D(x) + \delta_D(x)^{\alpha/2}}{\sqrt{t}} \wedge 1 \right) \left( \frac{m^{(2-\alpha)/2\alpha} \delta_D(y) + \delta_D(y)^{\alpha/2}}{\sqrt{t}} \wedge 1 \right) \\ \times \Psi_{d,\alpha,m,1/C_2}(t, x, y). \end{aligned}$$

These estimates are new even when  $D$  is the upper half space  $H$ . Observe that although  $H$  is invariant under scaling, global two-sided estimates on  $p_H^m(t, x, y)$  can not be derived through a scaling argument from the short time estimates which hold only for  $m \in (0, M]$  and  $t \in (0, T]$ .

For a fixed half-space-like  $C^{1,1}$  open set  $D$  with  $C^{1,1}$  characteristics  $(R, \Lambda_0)$  and  $H_a \subset D \subset H_b$ ,  $mD$  is still a half-space-like  $C^{1,1}$  open set but with  $C^{1,1}$ -characteristics  $(mR, \Lambda_0/m)$  and  $H_{ma} \subset mD \subset H_{mb}$ . So we can not use the scaling property

$$p_D^m(t, x, y) = m^{d/\alpha} p_{m^{1/\alpha}D}^1(mt, m^{1/\alpha}x, m^{1/\alpha}y)$$

to obtain sharp two-sided estimates for  $p_D^m(t, x, y)$  that are uniform in  $m \in (0, M]$  from that of  $p_D^1(t, x, y)$ .

These estimates are new even when  $D$  is the upper half space  $H$ . Observe that although  $H$  is invariant under scaling, global two-sided estimates on  $p_H^m(t, x, y)$  can not be derived through a scaling argument from the short time estimates which hold only for  $m \in (0, M]$  and  $t \in (0, T]$ .

For a fixed half-space-like  $C^{1,1}$  open set  $D$  with  $C^{1,1}$  characteristics  $(R, \Lambda_0)$  and  $H_a \subset D \subset H_b$ ,  $mD$  is still a half-space-like  $C^{1,1}$  open set but with  $C^{1,1}$ -characteristics  $(mR, \Lambda_0/m)$  and  $H_{ma} \subset mD \subset H_{mb}$ . So we can not use the scaling property

$$p_D^m(t, x, y) = m^{d/\alpha} p_{m^{1/\alpha}D}^1(mt, m^{1/\alpha}x, m^{1/\alpha}y)$$

to obtain sharp two-sided estimates for  $p_D^m(t, x, y)$  that are uniform in  $m \in (0, M]$  from that of  $p_D^1(t, x, y)$ .

A major part is to derive global sharp two-sided heat kernel estimates for  $X^m$  in a half-space.

Then, we use the push-inward technique developed in [Chen-Tokle, PTRF 2011] to extend it to half-space-like  $C^{1,1}$  open sets.

Passing  $m \downarrow 0$  recovers the sharp heat kernel estimates for symmetric  $\alpha$ -stable processes which were previously obtained in [Chen-Tokle, PTRF 2011].

- 1 Introduction
- 2 Relativistic stable processes
- 3 Estimates in General  $C^{1,1}$  open sets
- 4 Dirichlet Heat kernel estimates in half-space-like open set
- 5 Dirichlet Heat kernel estimates in exterior open set**

An open set  $D$  in  $\mathbb{R}^d$  is called an exterior open set if  $D^c$  is compact.

### Theorem [CKS3]

Suppose that  $d \geq 3$ ,  $M > 0$  and  $D$  is an exterior  $C^{1,1}$  open set in  $\mathbb{R}^d$ . Then there are constants  $c_i > 1$ ,  $i = 1, 2$ , such that for every  $m \in (0, M]$ ,  $t > 0$  and  $(x, y) \in D \times D$ ,

$$p_D^m(t, x, y) \leq c_1 \left( 1 \wedge \frac{\delta_D(x)}{1 \wedge t^{1/\alpha}} \right)^{\alpha/2} \left( 1 \wedge \frac{\delta_D(y)}{1 \wedge t^{1/\alpha}} \right)^{\alpha/2} \Psi_{d, \alpha, m, c_2}(t, x, y)$$

and

$$p_D^m(t, x, y) \geq c_1^{-1} \left( 1 \wedge \frac{\delta_D(x)}{1 \wedge t^{1/\alpha}} \right)^{\alpha/2} \left( 1 \wedge \frac{\delta_D(y)}{1 \wedge t^{1/\alpha}} \right)^{\alpha/2} \Psi_{d, \alpha, m, 1/c_2}(t, x, y).$$

and

$$p_D^m(t, x, y) \geq c_1^{-1} \left(1 \wedge \frac{\delta_D(x)}{1 \wedge t^{1/\alpha}}\right)^{\alpha/2} \left(1 \wedge \frac{\delta_D(y)}{1 \wedge t^{1/\alpha}}\right)^{\alpha/2} \Psi_{d,\alpha,m,1/c_2}(t, x, y).$$

The reason that we assume  $d \geq 3$  is that we used the transience of  $X^m$ . By Chung-Fuch's criterion for Lévy processes,  $X^m$  is transient if and only if  $d \geq 3$ .

The large time upper bound is relatively easy to establish. The main difficulty is in establishing the large time lower bound.
