Let  $L^\epsilon(t, x)$  be a two-time scale diffusion generator on the unit circle  $S^1$  of the form

$$L^\epsilon(t, x) = 1/\epsilon \cdot L_1(t, x) + L_2(t, x)$$

where  $L_i(t, x) = b_i(t, x)\partial_x + 1/2 \cdot a_i(t, x)\partial_{xx}$ .

$b_i(t, x), a_i(t, x) > 0$  are smooth functions on  $S^1$ . Let  $X_t^\epsilon$  satisfy the following stochastic differential equation :

$$\begin{aligned} dX_t^\epsilon &= (1/\epsilon \cdot b_1(t, X_t^\epsilon) + b_2(t, X_t^\epsilon))dt \\ &\quad + \sqrt{1/\epsilon \cdot a_1(t, X_t^\epsilon) + a_2(t, X_t^\epsilon)}dW_t \\ X_0^\epsilon &= \delta_x. \end{aligned}$$

There exists functions  $p_i(t, y)$  and  $q_{i,x}(t, y)$  such that

$$\sup_{t \leq T, y \leq 1} |p^\epsilon(t, y) - (\sum_0^n \epsilon^i p_i(t, y) + \sum_0^n \epsilon^i q_{i,x}(t/\epsilon, y))| = O(\epsilon^{n+1}).$$

- $p^\epsilon(t, y)$  is the distribution of  $X_t^\epsilon$ ,  $\sum_0^n \epsilon^i p_i(t, y)$  is called the regular part  $\sum_0^n \epsilon^i q_{i,x}(t/\epsilon, y)$  is the singular part of  $p^\epsilon(t, y)$  and  $|q_{i,x}(t, y)| \leq Ke^{-\gamma t}$  as  $t \rightarrow \infty$  uniformly over  $x, y$  and  $i \geq 1$ .
- $P_n^\epsilon(t, y) := \sum_0^n \epsilon^i p_i(t, y) + \sum_0^n \epsilon^i q_{i,x}(t/\epsilon, y)$ .
- Note that the regular part  $\sum_0^n \epsilon^i p_i(t, y)$  does not depend on  $x$  and  $p_0(t, y) = p(t, y)$  is the quasi-stationary distribution of  $L_1(t, x)$ .
- $b_i(t, x)$  and  $a_i(t, x) \in C^{n+1, 2(n+1)}[0, T] \times S^1$ .

There exists functions  $p_i(t, y)$  and  $q_{i,x}(t, y)$  such that

$$\sup_{t \leq T, y \leq 1} |p^\epsilon(t, y) - (\sum_0^n \epsilon^i p_i(t, y) + \sum_0^n \epsilon^i q_{i,x}(t/\epsilon, y))| = O(\epsilon^{n+1}).$$

- $p^\epsilon(t, y)$  is the distribution of  $X_t^\epsilon$ ,  $\sum_0^n \epsilon^i p_i(t, y)$  is called the regular part  $\sum_0^n \epsilon^i q_{i,x}(t/\epsilon, y)$  is the singular part of  $p^\epsilon(t, y)$  and  $|q_{i,x}(t, y)| \leq Ke^{-\gamma t}$  as  $t \rightarrow \infty$  uniformly over  $x, y$  and  $i \geq 1$ .
- $P_n^\epsilon(t, y) := \sum_0^n \epsilon^i p_i(t, y) + \sum_0^n \epsilon^i q_{i,x}(t/\epsilon, y)$ .
- Note that the regular part  $\sum_0^n \epsilon^i p_i(t, y)$  does not depend on  $x$  and  $p_0(t, y) = p(t, y)$  is the quasi-stationary distribution of  $L_1(t, x)$ .
- $b_i(t, x)$  and  $a_i(t, x) \in C^{n+1, 2(n+1)}[0, T] \times S^1$ .

There exists functions  $p_i(t, y)$  and  $q_{i,x}(t, y)$  such that

$$\sup_{t \leq T, y \leq 1} |p^\epsilon(t, y) - (\sum_0^n \epsilon^i p_i(t, y) + \sum_0^n \epsilon^i q_{i,x}(t/\epsilon, y))| = O(\epsilon^{n+1}).$$

- $p^\epsilon(t, y)$  is the distribution of  $X_t^\epsilon$ ,  $\sum_0^n \epsilon^i p_i(t, y)$  is called the regular part  $\sum_0^n \epsilon^i q_{i,x}(t/\epsilon, y)$  is the singular part of  $p^\epsilon(t, y)$  and  $|q_{i,x}(t, y)| \leq Ke^{-\gamma t}$  as  $t \rightarrow \infty$  uniformly over  $x, y$  and  $i \geq 1$ .
- $P_n^\epsilon(t, y) := \sum_0^n \epsilon^i p_i(t, y) + \sum_0^n \epsilon^i q_{i,x}(t/\epsilon, y)$ .
- Note that the regular part  $\sum_0^n \epsilon^i p_i(t, y)$  does not depend on  $x$  and  $p_0(t, y) = p(t, y)$  is the quasi-stationary distribution of  $L_1(t, x)$ .
- $b_i(t, x)$  and  $a_i(t, x) \in C^{n+1, 2(n+1)}[0, T] \times S^1$ .

For a bounded function  $f(x)$  on  $S^1$ , an unscaled function of the occupation time of  $X_t^\epsilon$  is defined as follows.

$$Z^\epsilon(t, f) = \int_0^t \left( f(X_s^\epsilon) - \int_0^1 f(y)p(s, y)dy \right) ds,$$

- A scaled function is defined as :

$$n^\epsilon(t, f) = 1/\sqrt{\epsilon} \cdot Z^\epsilon(t, f).$$

- We shall establish a weak law of large numbers :

$$\lim_{\epsilon \rightarrow 0} \epsilon Z^\epsilon(t, f)^2 = 0, \text{ and thus } Z^\epsilon(t, f) \rightarrow 0 \text{ in probability,}$$

- and asymptotic normality :

$$n^\epsilon(t, f) \rightarrow n(t, f) \text{ in } C[0, T] \text{ where } n(t, f) \text{ is Gaussian.}$$

For a bounded function  $f(x)$  on  $S^1$ , an unscaled function of the occupation time of  $X_t^\epsilon$  is defined as follows.

$$Z^\epsilon(t, f) = \int_0^t \left( f(X_s^\epsilon) - \int_0^1 f(y)p(s, y)dy \right) ds,$$

- A scaled function is defined as :

$$n^\epsilon(t, f) = 1/\sqrt{\epsilon} \cdot Z^\epsilon(t, f).$$

- We shall establish a weak law of large numbers :

$$\lim_{\epsilon \rightarrow 0} EZ^\epsilon(t, f)^2 = 0, \text{ and thus } Z^\epsilon(t, f) \rightarrow 0 \text{ in probability,}$$

- and asymptotic normality :

$$n^\epsilon(t, f) \rightarrow n(t, f) \text{ in } C[0, T] \text{ where } n(t, f) \text{ is Gaussian.}$$

The covariance function of  $n(\cdot, f)$ , independently of the initial point, is as follows.

$$En(t, f)^2 = 2 \int \int \int_0^t \int_0^\infty f(x)f(y)p(r, x)q_{0,r,x}(u, y)dudr dx dy$$

- Moreover,  $n(\cdot, f)$  has independent increment and  $E(n(t, f) \cdot n(s, f)) = En^2(t \min s, f)$ .

- Obviously,  $p_0(t, y) = p(t, y)$  is the quasi-stationary distribution of  $L_1(t, x)$
- $p_{i+1}(t, y)$  is solvable because  $\int_0^1 \partial_t p_i - L_2^* p_i(t, y) dy = 0$  which is the necessary and sufficient condition for Poisson equations to have a solution.
- To get the  $O(\epsilon^{n+1})$  estimate, we need to solve for  $p_{n+1}(t, y)$ .

For the singular part, we have  $(\partial_t - L^{\epsilon,*})(\sum_0^n \epsilon^j q_j(t/\epsilon, y)) = 0$ .  
For  $i = 1, 2$  and  $k = 0, 1, \dots, n+1$ , let

$$L_i^{*,k}(0, y)f = 1/2 \cdot \partial_{yy}(\partial_{t^k}^k a_i(0, y)f) - \partial_y(\partial_{t^k}^k b_i(0, y)f).$$

Let  $\tau = t/\epsilon$  and collect terms according to  $\epsilon^j$ , we have

$$\partial_\tau q_0(\tau, y) = L_1^*(0, y)q_0(\tau, y),$$

$$\begin{aligned} \partial_\tau q_1(\tau, y) &= L_1^*(0, y)q_1(\tau, y) + \tau L_1^{*,1}(0, y)q_0(\tau, y) \\ &\quad + L_2^*(0, y)q_0(\tau, y), \end{aligned}$$

$$\begin{aligned} \partial_\tau q_2(\tau, y) &= L_1^*(0, y)q_2(\tau, y) + \tau L_1^{*,1}(0, y)q_1(\tau, y) \\ &\quad + \tau^2 L_1^{*,2}(0, y)q_0(\tau, y) \end{aligned}$$

$$\begin{aligned} &+ L_2^*(0, y)q_1(\tau, y) + L_2^{*,1}(0, y)q_0(\tau, y), \\ &= \dots \end{aligned}$$

$$\begin{aligned} \partial_\tau q_i(\tau, y) &= L_1^*(0, y)q_i(\tau, y) + \sum_{j=1}^i \tau^j / j! \cdot L_1^{*,j}(0, y)q_{i-j}(\tau, y) \\ &\quad + \sum_{j=0}^{i-1} \tau^j / j! \cdot L_2^{*,j}(0, y)q_{i-j-1}(\tau, y), \end{aligned}$$

- A stochastic process  $X_t$  is  $\phi$ -mixing if for any  $t, s, A \in \mathcal{F}_0^t$  and  $B \in \mathcal{F}_{t+s}^\infty$ , we have

$$|P(B|A) - P(B)| \leq \phi(s).$$

- The process  $X_t^\epsilon$  satisfies the mixing condition with mixing rate  $K \cdot e^{-(\kappa/\epsilon)s}$ , i.e., for any  $\eta \in \mathcal{F}_{s+t}^\infty, |\eta| \leq 1$ ,

$$|E(\eta|\mathcal{F}_0^t) - E\eta| \leq K \cdot e^{-(\kappa/\epsilon)s}.$$

- Thus for any random variable  $\xi \in \mathcal{F}_0^t$  and  $|\xi| \leq 1$ , we have

$$|E(\xi\eta) - E\xi \cdot E\eta| \leq K \cdot e^{-(\kappa/\epsilon)s}.$$

Two simple estimates,

$$\int_D e^{-\kappa(r_2-r_1)/\epsilon} e^{-\kappa(r_4-r_3)/\epsilon} dr_1 dr_2 dr_3 dr_4$$

$$\leq \int_t^{t+s} s\epsilon^2/\kappa^2 (1 - e^{-\kappa(r_4-t)/\epsilon}) dr_4 \leq s^2\epsilon^2/\kappa^2$$

and

$$\int_D e^{-\kappa(r_4-r_1)/2\epsilon} dr_1 dr_2 dr_3 dr_4 \leq \int_D e^{-\kappa(r_4-r_2)/2\epsilon} dr_1 dr_2 dr_3 dr_4$$

$$\leq 4s^2\epsilon^2/\kappa^2.$$

We therefore conclude that  $E(\bar{n}^\epsilon(t+s, f) - \bar{n}^\epsilon(t, f))^4 \leq Ks^2$   
for every  $\epsilon$  and  $\bar{n}^\epsilon(\cdot, f)$  is tight in  $C[0, T]$ .

Consider  $n(t_4, f) - n(t_3, f)$  and  $n(t_2, f) - n(t_1, f)$  where  $t_4 > t_3 > t_2 > t_1 \geq 0$ . By the mixing property, we have

$$\begin{aligned} & |Ee^{iu_1(n^\epsilon(t_4, f) - n^\epsilon(t_3, f)) + iu_2(n^\epsilon(t_2, f) - n^\epsilon(t_1, f))} \\ & - Ee^{iu_1(n^\epsilon(t_4, f) - n^\epsilon(t_3, f))} Ee^{iu_2(n^\epsilon(t_2, f) - n^\epsilon(t_1, f))}| \\ & \leq Ke^{-\kappa(t_3 - t_2)/\epsilon} \rightarrow 0 \text{ as } \epsilon \rightarrow 0 \end{aligned}$$

for any  $u_1, u_2 \in \mathbb{R}$ .

Short Paper  
TitleAuthor,

But

$$\begin{aligned}
& |Ee^{iu_1(n^\epsilon(t_4, f) - n^\epsilon(t_3, f)) + iu_2(n^\epsilon(t_2, f) - n^\epsilon(t_1, f))} \\
& - Ee^{iu_1(n^\epsilon(t_4, f) - n^\epsilon(t_3, f))} Ee^{iu_2(n^\epsilon(t_2, f) - n^\epsilon(t_1, f))}| \\
& \rightarrow |Ee^{iu_1(n(t_4, f) - n(t_3, f)) + iu_2(n(t_2, f) - n(t_1, f))} \\
& - Ee^{iu_1(n(t_4, f) - n(t_3, f))} Ee^{iu_2(n(t_2, f) - n(t_1, f))}| \text{ as } \epsilon \rightarrow 0,
\end{aligned}$$

we thus have

$$\begin{aligned}
& Ee^{iu_1(n(t_4, f) - n(t_3, f)) + iu_2(n(t_2, f) - n(t_1, f))} \\
& = Ee^{iu_1(n(t_4, f) - n(t_3, f))} Ee^{iu_2(n(t_2, f) - n(t_1, f))}.
\end{aligned}$$

This shows the independence of  $n(t_4, f) - n(t_3, f)$  and  $n(t_2, f) - n(t_1, f)$ . Let  $t_3 \rightarrow t_2$  and then complete the proof.

Continuous sample paths and independent increments imply that  $n(t, f)$  is a Gaussian process (with mean 0). We now compute its covariance. Since

$$\begin{aligned} & EZ^\epsilon(t, f)^2 \\ &= 2\epsilon \int_0^1 \int_0^1 \int_0^t \int_0^\infty f(x)f(y)p(r, x)q_{0,r,x}(u, y)dudr dx dy \\ &+ O(\epsilon^2), \end{aligned}$$

we obviously have that for two non-negative functions  $f$  and  $g$ ,

$$\begin{aligned} & EZ^\epsilon(t, f) \cdot Z^\epsilon(t, g) \\ &= \epsilon \int_0^1 \int_0^1 \int_0^t \int_0^\infty f(x)g(y)p(r, x)q_{0,r,x}(u, y)dudr dx dy \\ &+ \epsilon \int_0^1 \int_0^1 \int_0^t \int_0^\infty f(y)g(x)p(r, x)q_{0,r,x}(u, y)dudr dx dy \\ &+ O(\epsilon^2). \end{aligned}$$

It follows that

$$\begin{aligned}
 & \lim_{\epsilon \rightarrow 0} \text{En}^\epsilon(t, f)^2 \\
 &= 2 \int_0^1 \int_0^1 \int_0^t \int_0^\infty f(x)f(y)p(r, x)q_{0,r,x}(u, y)du dr dx dy \\
 &= \text{En}(t, f)^2.
 \end{aligned}$$

The covariance function of  $n(t, f)$  is thus  
 $\text{En}(t, f)\text{En}(s, f) = \text{En}(\min\{t, s\}, f)^2.$
