# QSDs

A Quasi-Stationary Distribution ( in short QSD) for X is a probability measure supported on  $(0, \infty)$  satisfying for all  $t > 0$ ,

$$
\mathsf{P}_\nu(\mathsf{X}(\mathsf{t})\in\mathsf{A}|\mathsf{T}>\mathsf{t})=\nu(\mathsf{A}),\,\,\forall\,\,\text{borel}\ \ \text{set}\ \ \mathsf{A}\subseteq (0,\infty).
$$

where

$$
T=\inf\{t\geq 0, X(t)=0\}
$$

<span id="page-2-0"></span> $2QQ$

- Both (i) and (ii) are known only for finite Markov processes, and for the subcritical Markov Branching Process(MBP)
- For a Birth and death process, Erik A. VAN DOORN (Adv.Appl.Prob.23, 683-700,1991) obtained Proposition (i) if  $S = \infty$ , then either  $\lambda_C$  (Kingman's decay parameter  $)=0$  and there is no QSD, or  $\lambda_c > 0$  and there is a one-parameter family of QSDs, Viz,  $\{q_i(x)\}, 0 < x \leq \lambda_C\}$ . (ii) If  $S < \infty$ , then  $\lambda \subset 0$  and there is precisely one  $QSD$ , Viz,  $\{q_i(\lambda_C)\}$

 $2Q$ 

 $4\Box$   $\rightarrow$   $\Box$   $\Box$   $\rightarrow$   $\Box$   $\rightarrow$   $\Box$   $\rightarrow$ 

• Let  $X_t$  be a continuous-time Markov chain in  $I = \{0\} \cup \{1, 2, \ldots\}$  such that 0 is an absorbing state. Let  $C = \{1, 2, ...\}$ . Denote by  $Q = (q_{ii})$  the q-matrix (transition rate matrix) and  $P(t)=(P_{ij}(t))$  the transition function.  $X_t$  is stochastically monotone if and only if  $\sum_{j\geq k} P_{ij}(t)$  is a nondecreasing function of *i* for every fixed  $k \in I$  and  $t > 0$ . We assume that all states other than 0 form an irreducible class and that Q is totally stable, conservative and regular, that is,  $q_i = \sum_{i \neq j} q_{ij} < \infty,$  and the minimal process  ${X_t}_{t>0}$  corresponding to Q is an honest process. We further define  $T = \inf\{t \ge 0 : X_t = 0\}$ , the absorption time at 0. So  $X_t = 0$  for any  $t > T$ .

 $\Omega$ 

For continuous-time general Markov chains, P.A.Ferrari, H.Kesten,S.Martinez, and P.Picco (The Annals of Probability 1995,Vol.23, No.2,501-521.) obtained Proposition 2 Assume that

$$
\lim_{i\to\infty} P_i(T
$$

and that  $P_i(T < \infty) = 1$  for some (and hence all) *i*. Then a necessary and sufficient condition for the existence of a QSD is that

$$
E_i(e^{\theta \mathcal{T}})<\infty
$$

for some  $\theta > 0$  and some  $i \in \mathcal{C}$  (and hence for all i).

 $\Omega$ 

 $(1, 1)$   $(1, 1)$   $(1, 1)$   $(1, 1)$   $(1, 1)$   $(1, 1)$   $(1, 1)$   $(1, 1)$   $(1, 1)$ 

• Our result is Theorem 1 Assume that

$$
\lim_{i\to\infty}E_iT=\infty,
$$

and that  $P_i(T < \infty) = 1$  for some (and hence all) *i*. Then a necessary and sufficient condition for the existence of a QSD is that

$$
E_i(e^{\theta T}) < \infty
$$

for some  $\theta > 0$  and some  $i \in C$  (and hence for all i). When it holds, There exists a family of QSDs.

 $\Omega$ 

 $4\Box$   $\rightarrow$   $\overline{AB}$   $\rightarrow$   $\rightarrow$   $\overline{B}$   $\rightarrow$   $\rightarrow$   $\overline{B}$   $\rightarrow$ 

For stochastically monotone Markov chains, we discuss the existence, uniqueness and domain of attraction of QSDs. Theorem 2 Assume  $Q$  is regular and conservative, and  $X_t$  is stochastically monotone,

(i) If  $\lim_{i\to\infty} E_iT = \infty$ , then there exists a QSD if and only if

$$
E_i(e^{\theta T}) < \infty
$$

for some  $\theta > 0$  and some  $i \in \mathcal{C}$  (and hence for all i). (ii) If  $\lim_{i\to\infty} E_i \mathcal{T} < \infty$ , and the set  $N_0 = \{i \in \mathcal{C} : q_{i0} > 0\}$  is finite, then there is a unique QSD .Moreover, the unique QSD  $\rho=\{\rho_j, j\in \mathcal{C}\}$  attracts all initial distributions that supported in C, that is, for any probability measure  $\nu = \{\nu_i, i \in \mathcal{C}\},$  $\rho_i = \lim_{t \to \infty} P_{\nu}(\mathbf{X}_t = \mathbf{i} | \mathbf{T} > \mathbf{t}), \quad \mathbf{j} \in \mathbf{C}.$ 

 $A \cup B \cup A \cup B \cup A \cup B \cup A \cup B \cup A$
